Question	Answer	Assessment Criteria	Rationales
1	C	1.1.1	A. Incorrect. The scenario is not primarily about iteration or release cycles, it is about validating value before prioritization. "Each iteration is released only after user feedback; change plans embed UX evaluation alongside technical checks." Ref 4.1.3, Table 4.2 B. Incorrect. This principle relates to applying automation where it improves experience. The scenario does not describe automation or efficiency improvement; it describes value-based prioritization. "Different disciplines co-design solutions; automation is applied where it genuinely improves user and staff experience." Ref 4.1.3, Table 4.2 C. Correct. The scenario describes evaluating proposed changes based on whether they solve real user problems, improve service outcomes, and strengthen long-term benefits. This directly reflects the principle of ensuring that all activities contribute to meaningful value for customers and service providers. "Positive impact occurs when services enable outcomes, optimize cost, or reduce risk." Ref 2.2.1 D. Incorrect. The scenario does not emphasize simplification; it emphasizes ensuring that changes create real value. This principle emphasizes simplicity in delivery: "Teams ship thin slices, simplifying flows based on real usage rather than speculative feature completeness." Ref 4.1.3, Table 4.2
2	C	1.1.2	A. Incorrect. It is true that digital products rely on software and virtual infrastructure. Digital products "depend on digital resources (software and virtual infrastructure)". Ref 2.1 B. Incorrect. It is true that digital products can be diagnosed without on-site intervention. They "can be diagnosed, fixed, and improved remotely". Ref 2.1 C. Correct. Digital products are different to non-digital ones and physical delivery is a characteristic of non-digital products. Non-digital products: "depend on physical delivery", while digital products "can be delivered instantly and digitally". Ref 2.1 D. Incorrect. It is true that digital products are used and improved simultaneously. They "are developed, improved, and used simultaneously. Ref 2.1
3	D	1.1.4	A. Incorrect. The scope of lifecycle management activities is not fixed; it varies depending on the organization's operating model and responsibilities. "Different organizations are responsible for different stages of the Product and Service Lifecycle. The scope of responsibility depends on an organization's business model and defines the corresponding operating model." This directly contradicts the statement that lifecycle management activities have a fixed scope and order. Ref 11.3.2

Question	Answer	Assessment Criteria	Rationales
			B. Incorrect. Value chain activities are not performed in a strict, predetermined sequence; they are adapted and combined based on real-world workflows. "Value streams: are the actual sequence of activities performed, rather than a predetermined blueprint." This clearly shows that activities are not always executed in a strict sequence, but vary depending on context and value stream design. Ref 11.4 C. Incorrect. Operate, deliver, and support do not necessarily occur one after another in a rigid sequence; lifecycle responsibilities and flows may vary depending on organizational role and integration. "However, when the product vendor and service provider roles are played by two organizations [...] the focus of their concerns at each stage of the lifecycle changes [...]." This demonstrates that lifecycle stages—including operate, deliver, and support—are not universally sequential but depend on role distribution and operating model. Ref 2.1.1 D. Correct. Lifecycle management activities should be managed in a holistic and integrated way. "The ITIL Product and Service Lifecycle includes eight stages. To manage digital products and services throughout the lifecycle, organizations need to develop relevant management capabilities (ITIL describes them as management practices) and apply them in the context of the organization's operating model. The operating model's core is its value chain: a set of activities that enables value through the provision of a product or service." This confirms that lifecycle management is applied within the broader value chain and operating model context, supporting an integrated and holistic approach. Ref 2.1.2
4	B	1.2.5	A. Incorrect. Creating or testing the solution is not described in the scenario. "The purpose of the 'build activity is to develop, integrate, and test digital products and services, transforming designs into functional solutions." Ref 6.1.1 B. Correct. The scenario shows deployment of the solution into the live environment, including onboarding and preparing users and stakeholders, and moving tested solutions into live environments. "The purpose of the 'transition' activity is to seamlessly introduce new or updated products and services into operational environments and to ensure the effective onboarding/offboarding of suppliers." Ref 7.1.1 C. Incorrect. 'Operate' focuses on ongoing management after deployment. 'Transition' is the step that makes products available before 'operate' begins: "The purpose of the 'operate' activity is to

Question	Answer	Assessment Criteria	Rationales
			maintain and monitor digital products and services and supporting systems, ensuring optimal performance and reliability." Ref 8.1.1 D. Incorrect. Support focuses on restoring service and helping users. "Restoring normal product operation and service delivery in case of incidents", while the 'transition' activity seamlessly introduces "new or updated products and services into operational environments and to ensure the effective onboarding/offboarding of suppliers." Ref 2.1.1, Table 2.1, 7.1.1
5	A	1.2.7	A. Correct. The scenario describes agreed service actions performed for a user during service consumption. "The purpose of the 'deliver' activity is to provide products and services to users, manage user onboarding/offboarding, maintain service quality standards, and gather consumer feedback." Ref 9.1.1 B. Incorrect. 'Transition' focuses on moving products or services into the live environment. "Transitioning tested products into live environment." Ref 2.1.1, Table 2.1 C. Incorrect. 'Operate' focuses on maintaining product performance. "Ongoing operation and maintenance of the products' hardware, software, and data; Monitoring of the product health; Capturing and processing relevant events." Ref 2.1.1, Table 2.1 D. Incorrect. 'Support' focuses on restoring service and handling incidents. "Restoring normal product operation in case of incidents" Ref 2.1.1, Table 2.1
6	D	1.2.8	A. Incorrect. 'Deliver' focuses on "performing the agreed service actions, including fulfilment of service requests". Ref 2.1.1, Table 2.1 B. Incorrect. 'Transition' is about bringing products into a live environment. "Transitioning tested products into live environment." Ref 2.1.1, Table 2.1 C. Incorrect. 'Operate' focuses on maintaining product performance. "Operate: Ongoing operation and maintenance of the products' hardware, software, and data; Monitoring of the product health; Capturing and processing relevant events." Ref 2.1.1, Table 2.1 D. Correct. The scenario describes responding to user queries, restoring service access, and investigating monitoring alerts to resolve underlying causes. This directly aligns with the purpose of the 'support' activity, which focuses on restoring normal service operation when disruptions occur. "The purpose of the 'support' activity is to restore normal service operation (ideally, before incidents have adverse impact on service users)." Ref 10.1.1

Question	Answer	Assessment Criteria	Rationales
7	B	2.1.3	A. Incorrect. The scenario focuses on understanding stakeholder expectations and documenting requirements. Architecture management concerns optimizing product and service architectures, rather than defining stakeholder needs. "Architecture management: Developing, agreeing, planning, and continually optimizing the organization's product and service architectures." Ref 3.3, Table 3.3 B. Correct. The scenario describes working with stakeholders to understand expectations, identify unmet needs, and document requirements. This directly aligns with defining stakeholder needs and requirements. "Business analysis: Defining stakeholder needs and requirements." Ref 3.3, Table 3.3 C. Incorrect. Portfolio management concerns optimizing product and service portfolios. The scenario focuses on gathering and documenting stakeholder requirements rather than managing the portfolio itself. "Portfolio management: Developing, agreeing, planning, and continually optimizing the organization's product and service portfolios." Ref 3.3, Table 3.3 D. Incorrect. Risk management concerns defining and communicating risk appetite and approach. The scenario centers on understanding stakeholder expectations and documenting requirements, not on establishing risk parameters. "Risk management: Defining, agreeing, and communicating the organization's risk appetite and risk management approach." Ref 3.3, Table 3.3
8	B	2.2.2	A. Incorrect. This is part of the assessment step, not the next step. Stakeholder involvement happens while assessing the product context. Engaging diverse stakeholders is typically part of the earlier exploration work. The emphasis is on broadening perspective during discovery to ensure a holistic understanding of needs and context. However, in this scenario, Omar has already convened a cross-functional working group and revisited personas. This suggests that stakeholder perspectives have already been incorporated. Returning to broaden engagement would repeat earlier activities rather than advance the work. "Even when an organization has a product-based organizational structure [...] this step is likely to involve other stakeholders." Ref 3.2.1.1 B. Correct. In the scenario, ICR has already reviewed the broader context, revisited personas, and clarified the problems users face in different markets. This indicates that the exploratory work to understand the situation has been completed. The book explains that once context, target segments, and needs are understood, the next step is to synthesize those findings into a clear

Question	Answer	Assessment Criteria	Rationales
			strategic direction. Insights gathered during exploration should be translated into structured intent that aligns business goals, user value, and feasibility. This direction then becomes the foundation for prioritization and downstream planning. Therefore, converting the insights into a clearly articulated product direction logically follows from the activities described. “The high-level workflow of the ‘discover’ activity comprises four steps: assess the product context; agree direction and objectives; prioritize actions and allocate resources; communicate changes in the product roadmap.” Ref 3.2 C. Incorrect. Examining dependencies across existing services and components is generally associated with architectural refinement, portfolio review, or preparation for design and build. This type of analysis is part of assessing feasibility and implementation implications. Since the scenario has not yet translated insights into a defined direction or initiative, it would be premature to examine structural interdependencies before clarifying what is actually being proposed. This answer relates to assessing internal capabilities during context assessment, not the step that follows it. “Discover” begins with an assessment of the current environment. Inputs include strategic direction, a PESTLE analysis, portfolio reviews, current roadmaps, backlog assessments [...].” Ref 3.2.1.1 D. Incorrect. This corresponds to the final step of the workflow (communicating changes in the roadmap) which occurs after agreeing direction and prioritizing actions. Communicating the purpose and expected value of an initiative typically occurs once there is a defined proposal or direction to present. Alignment and communication activities follow the articulation of strategic intent. In the scenario, ICR has not yet formed a clear direction or defined initiative. Without that clarity, there is no structured rationale to communicate, making this option premature. Roadmap communication happens after direction is agreed and priorities are adjusted. Since alignment on direction has not yet occurred, communication would be premature. “The high-level workflow of the ‘discover’ activity comprises four steps: assess the product context; agree direction and objectives; prioritize actions and allocate resources; communicate changes in the product roadmap.” Ref 3.2

Question	Answer	Assessment Criteria	Rationales
9	D	2.3.1	A. Incorrect. Enhancing cooperation helps alignment, but the failure described stems from lack of validation and evidence-based testing. "Embrace cross-functional collaboration continually." Ref 3.4.3, Table 3.5 B. Incorrect. Reducing formal evaluation would worsen the issue, as rigorous validation is required. "Frequent validation allows designers to surface issues early, iterate swiftly, and converge on solutions that demonstrably meet user expectations." Ref 4.4.3, Table 4.5 C. Incorrect. Increasing leadership involvement does not address the core issue of decisions being opinion-based rather than evidence-based. "Strong leadership advocacy and resource commitment." Ref 4.4.1 D. Correct. The scenario shows that decisions were based primarily on opinion and past experience, leading to poor adoption. To avoid this, the provider should focus on evidence-based validation something which defines assumptions clearly and measures outcomes using performance indicators rather than relying on intuition. "Decisions are grounded in measurable data rather than intuition." Ref 3.4.1
10	D	2.3.2	A. Incorrect. Strong leadership sponsorship refers to visible support, direction, and resource backing from senior leaders. In the scenario, a senior leader actively supports and accelerates the initiative. While the decision was flawed, sponsorship itself is not missing; in fact, it is present. The issue lies not in absence of sponsorship but in how the decision was made. The following requirement: "executive sponsorship engagement counts relevant sponsor touchpoints [...] supporting strategic visibility and resource commitment" was present. The issue was not lack of sponsorship, but poor validation. Ref 3.4.2 B. Incorrect. Scalable infrastructure and practices relate to the organization's ability to support growth, maintain performance, and ensure reliable operations as usage increases. The scenario does not describe technical instability, performance issues, or scaling constraints. The problem is low adoption and unchanged satisfaction, not infrastructure failure. Therefore, this recommendation is not the one being neglected. Scalable infrastructure and operational practices focus on reliability, infrastructure, and performance. "Site Reliability Engineering (SRE): A discipline that incorporates aspects of software engineering and applies them to infrastructure and operations problems with the goal of creating ultra-scalable and highly reliable software systems." Ref 8.1 C. Incorrect. Effective supplier relationship management concerns how external partners are governed, aligned, and managed to support service

Question	Answer	Assessment Criteria	Rationales
			outcomes. The scenario does not mention third-party constraints, integration problems, or supplier misalignment. The challenge arises from internal decision-making rather than supplier performance. As a result, this recommendation is not the one that has been ignored. Supplier management is the “practice of ensuring that an organization’s suppliers and their performance levels are managed appropriately to support the provision of seamless quality products and services”. Ref Glossary D. Correct. Leadership pushed the feature forward based on opinion rather than validating assumptions with data. This shows a failure to apply evidence-based decision-making, which requires using measurable data and insights to guide product decisions instead of relying solely on senior judgement. “Use data alongside qualitative insights.” Ref 3.4.3, Table 3.5
11	C	3.1.1	A. Incorrect. Standardizing a single framework would improve consistency, but the core problem is that decisions were based on assumptions rather than real user evidence. “There are numerous approaches to product and service design, and organizations combine them to fit the context and optimize the results.” Ref 4.1.3 B. Incorrect. Releasing changes faster would not solve the root issue if improvements are still based on internal assumptions instead of user validation. “Frequent validation allows designers to surface issues early, iterate swiftly, and converge on solutions that demonstrably meet user expectations.” Ref 4.4.3, Table 4.5 C. Correct. The issue arose because the redesign was driven by internal assumptions and limited stakeholder feedback rather than real user insight. To prevent low adoption and usability problems, design decisions must be grounded in validated understanding of user behaviours, contexts, and needs. “Service providers and users should be actively involved in capturing requirements, validating assumptions, and providing feedback on early designs and prototypes, so that the product reflects real-world usage patterns, support scenarios, and operational constraints.” Ref 4.1.2.1 D. Incorrect. Increasing governance may enforce standards, but governance does not replace understanding real user behaviours and needs. “Compliance is an essential pillar of the governance model.” Ref 1.6

Question	Answer	Assessment Criteria	Rationales
12	C	3.1.2	A. Incorrect. Defining responsibilities to reduce misuse relates more to security and compliance than to managing organizational adoption and behavioural change. "Information security management: Designing optimal solutions for the required level of information security." Ref 4.3, Table 4.3 B. Incorrect. Encouraging feedback supports continual improvement, but the scenario focuses on proactively designing new roles and ways of working before adoption. "Discover' is a learning loop [...]. Continuous iteration [...] allows teams to adapt products to evolving user needs." Ref 3.1.3 C. Correct. The scenario describes significant shifts in roles, skills, and ways of working. Organizational change management supports the design activity by ensuring that necessary organizational adjustments — including roles, processes, and behaviours — are deliberately designed so the service can be effectively operated and adopted. "Organizational change management: Designing organizational changes required for product operation, and service delivery and consumption." Ref 4.3, Table 4.3 D. Incorrect. Eliciting and documenting user needs aligns more closely with business analysis and discovery activities rather than managing organizational change and adoption. Business analysis plays a critical role early in the lifecycle, as it supports understanding stakeholder needs and shaping direction. "Business analysis: Capturing, analysing, and communicating needs and requirements of customers, users, and other relevant stakeholders. Proposing viable solutions to meet the captured needs and requirements." Ref 4.3, Table 4.3
13	A	3.2.2	A. Correct. The scenario describes reviewing the roadmap and backlog, analysing usage data and trends, benchmarking competitors, and revisiting interviews and surveys to confirm whether earlier insights remain valid. These actions reflect validating demand, reassessing opportunity size, and ensuring strategic alignment before committing further investment. This aligns with analysing product demand and strategy, where quantitative and qualitative inputs are synthesized to confirm that the proposed direction remains relevant and commercially justified. These activities form the first step of 'design': "Inputs may include the product roadmap, backlogs, strategic objectives, stakeholder feedback, performance data, and prototype validation findings from the 'discover' activity." Ref 4.2.1.1 B. Incorrect. This option refers to mobilizing or setting up the design effort itself, such as defining

Question	Answer	Assessment Criteria	Rationales
			governance, roles, and working methods. The scenario does not describe preparing teams, allocating resources, or organizing structured workshops. Instead, it focuses on reviewing evidence and validating demand. Therefore, this option reflects an earlier mobilization activity rather than what is occurring presently. The design step described in the book is about analysing demand first, not organizing logistics. 'Design' "Inputs may include the product roadmap, backlogs, strategic objectives, stakeholder feedback, performance data, and prototype validation findings from the 'discover' activity." Ref 4.2.1.1 C. Incorrect. This relates to organizing and preparing for a structured 'design' activity. The scenario clearly shows that structured analysis is already underway. The team is not organizing the effort; they are actively examining data and validating assumptions. This does not match the described activity. It corresponds to the 'build' activity, not 'design'. "Once the appropriate build units and build specifications are documented, scheduled, and resources are assigned, the coding of the product begins." Ref 6.2.1.3 D. Incorrect. This option refers to sharing finalized design specifications and implementation plans. In the scenario, no solution has been finalized, and no implementation plan is being communicated. The team is still validating whether the opportunity is viable. Communication of agreed specifications would occur after demand validation and strategic direction are confirmed. 'Design' "Stakeholder alignment is critical at this stage. A concise demand-strategy brief (typically a slide deck or one-page summary) that outlines key metrics, strategic levers, and success criteria is presented to sponsors." Ref 4.2.1.1
14	A	3.3.2	A. Correct. The solution was designed primarily with a focus on technical feasibility and speed, creating uncertainty about how it will perform in live environments. To reduce the risk of rework, disruption, and poor adoption, the organization should strengthen collaboration across disciplines during design to ensure operational, support, and user considerations are built in early. This reduces downstream issues and improves readiness for live use. "Ensure that compatibility and supportability are designed in from the start rather than added later." Ref 4.1.2.3 B. Incorrect. While leadership reviews may improve visibility and governance oversight, they do not directly address the operational risks described. Senior leadership feedback typically focuses on strategic alignment and delivery progress rather than

Question	Answer	Assessment Criteria	Rationales
			detailed run-time support considerations. Increasing review cadence may accelerate decisions, but it does not inherently reduce the risk of operational gaps or service disruption once the solution goes live. Senior leadership reviews do not directly address operational risks: "Executive sponsorship engagement counts relevant sponsor touchpoints (briefings, demo reviews, communications) within 'discover', supporting strategic visibility and resource commitment." Ref 3.4.2 C. Incorrect. Comprehensive documentation can support clarity and coordination; however, documentation alone does not validate whether the design will perform effectively in live operational conditions. If operational perspectives have not been incorporated into the design itself, documenting the existing solution may simply formalize assumptions that later prove problematic. This action does not address the root concern about live performance and adoption risk. "At the same time, lack of attention to operations during the 'design', 'build', and 'transition' activities is likely to cause service disruptions. Effective product operation is a key factor of service reliability." Ref 8.1 D. Incorrect. A limited rollout can reveal issues in real conditions, but it does so reactively, after the solution has already progressed into use. While pilots are valuable, the CIO's objective is to reduce risk before the solution advances further. Waiting until early use to discover operational gaps increases the likelihood of rework and service disruption. Engaging operational teams earlier in the design phase is a more preventive approach. Operational risks should be addressed before release, not discovered after: "At the same time, lack of attention to operations during the 'design', 'build', and 'transition' activities is likely to cause service disruptions." Ref 8.1
15	C	4.1.2	A. Incorrect. Architecture management ensures technical alignment and scalability, not provider selection or contract negotiation. It plays a critical role in product design. "Architecture management: Providing architecture standards and requirements for suppliers' resources, products and services." Ref 5.3, Table 5.2 B. Incorrect. Service financial management focuses on financial assessment rather than managing supplier relationships and agreements. "Service financial management: Registering, tracking, and reporting on the use of obtained resources and services in the organization's products and services." Ref 5.3, Table 5.2 C. Correct. The scenario describes evaluating potential service providers, selecting a supplier, negotiating agreements, and ensuring contractual terms support collaboration and

Question	Answer	Assessment Criteria	Rationales
			service expectations. These activities directly align with the purpose of supplier management within the 'acquire' activity, which governs sourcing decisions, supplier selection, and contractual arrangements. "Supplier management: Identifying, selecting, and onboarding suppliers. Managing contracts and agreements with suppliers." Ref 5.3, Table 5.2 D. Incorrect. IT asset management tracks and provides information about assets but does not manage external supplier selection or contractual terms. "IT asset management: Registering, tracking, and reporting on the IT assets." Ref 5.3, Table 5.2
16	A	4.2.2	A. Correct. This is the correct next step. The scenario shows that sourcing options have already been evaluated and a preferred approach has been selected. Before resources are made available, ICR needs to ensure that expectations, responsibilities, and conditions are clearly defined and enforceable. This provides clarity, manages risk, and creates a reliable basis for moving forward with the selected parties. "Negotiating the contractual framework transforms a selected sourcing option into a legally binding relationship that protects both parties' interests." Ref 5.2.1.3 B. Incorrect. This action would be appropriate earlier in the process, while comparing and selecting sourcing options. The scenario states that suitability, risks, and alignment have already been agreed, so reassessing options would unnecessarily repeat work and delay progress rather than moving the initiative forward. "Having a well-defined set of requirements, the next step is to explore the marketplace for optimal sourcing pathways. The sourcing analyst conducts a systematic market scan, leveraging spend analytics, supplier databases, and industry reports to compile a shortlist of qualified vendors." Ref 5.2.1.2 C. Incorrect. Validating capabilities is an important consideration, but in this scenario, it is implied that suitability and risks have already been reviewed as part of the selection process. At this point, the priority is not further evaluation but ensuring that agreed expectations and responsibilities are clearly established before proceeding. "First, an organization must translate its strategic objectives, product roadmaps, prioritized backlogs, and validated designs into a concrete, actionable set of resource requirements." Ref 5.2.1.1 D. Incorrect. Updating records supports traceability and governance, but it does not, by itself, ensure that expectations and responsibilities are clear and enforceable. This activity typically follows or accompanies formal agreements rather than replacing them, and it should not be the immediate

Question	Answer	Assessment Criteria	Rationales
			next step on its own. "The timely, transparent communication of resource or service readiness is essential to maintain trust with internal requestors and to keep the roadmap and backlog iterations on schedule." Ref 5.2.1.5
17	B	4.3.1	A. Incorrect. Expanding risk assessments improves compliance, but the scenario highlights misalignment and fragmented decision-making rather than regulatory gaps. "Implementing structured risk-assessment methodologies [...] helps safeguard continuity, protect brand reputation, and ensure adherence to internal policies and external regulations". Ref 5.4.1 B. Correct. Procurement must be strategically aligned to avoid short-term, fragmented sourcing. "The 'acquire' activity [...] must be tightly coupled to the broader strategy, ensuring that sourcing decisions directly support the organization's financial, operational, and sustainability objectives". Ref 5.4.1 C. Incorrect. Improving negotiation skills strengthens capability but does not resolve duplication or lack of strategic visibility. "Procurement effectiveness depends on a workforce equipped with negotiation expertise, market intelligence, and analytical acumen." Ref 5.4.1 D. Incorrect. Automation increases efficiency, but the problem described is governance and alignment, not manual processing delays. "Leveraging e-procurement solutions [...] streamlines routine tasks, reduces manual errors, and accelerates cycle times". Ref 5.4.1
18	B	4.3.2	A. Incorrect. Traceability and accountability ensure that acquisition decisions are transparent and responsibilities are clear. While valuable for governance and oversight, this action does not inherently prevent restrictive contract terms or supplier lock-in. Even with strong accountability, a rigid multi-year agreement could still be signed if flexibility is not intentionally designed into the sourcing model. "Clearly document who selects, approves, signs off, and ultimately owns the performance of each purchased item. Including acquisition outcomes in product retrospectives reinforces responsibility and provides a structured forum for reviewing what worked and what did not." Ref 5.4.3 B. Correct. The organization faced difficulty adapting its sourcing strategy due to contractual penalties. This indicates that flexibility was not sufficiently considered during acquisition planning. Designing contracts and sourcing models to accommodate evolving business needs reduces the risk of vendor lock-in and costly exit barriers. "Design contracts and sourcing models

Question	Answer	Assessment Criteria	Rationales
			with flexibility in mind, allowing adjustments as business needs evolve.” Ref 5.4.3 C. Incorrect. Ensuring that acquisition outputs meet the needs of downstream stakeholders improves alignment and operational effectiveness. However, the scenario does not describe dissatisfaction with the initial service capabilities. The issue arises from evolving needs over time and the inability to adapt contractually. Verification at the time of acquisition would not necessarily protect against future shifts in demand or technology. “Verify that acquisition outputs satisfy the needs of all downstream professionals (APIs, integrations, SLAs).” Ref 5.4.3, Table 5.4 D. Incorrect. Involving procurement and supplier specialists early can strengthen negotiation and contract structure. However, expert involvement alone does not guarantee contractual flexibility unless flexibility is explicitly designed as an objective. Early engagement improves process quality but does not directly address the structural rigidity that caused the problem. “Executive sponsorship and cross-functional governance.” Ref 5.4.3, Table 5.4
19	A	5.1.2	A. Correct. The scenario focuses on building access controls and data protection directly into the product and verifying them during testing. This aligns with information security management in the build stage. “Information security management: Embedding information security controls into the products.” Ref 6.3, Table 6.2 B. Incorrect. Collecting feedback from incidents relates to post-release operational improvement, not secure build and validation. “Effective operations require a disciplined incident response framework [...]” Ref 8.4.1 C. Incorrect. Defining acceptable user behaviours relates more to governance and compliance during service use, not embedding controls during build. A secure digital product requires a “security-first culture and compliance governance” approach to ensure that data protection and regulatory requirements are embedded throughout its lifecycle. Ref 8.4.3, Table 8.4 D. Incorrect. Documenting user needs supports discovery and design, not secure control implementation during build. “Designers can surface the unmet needs that truly drive purchase or adoption decisions.” Ref 4.2.1.1

Question	Answer	Assessment Criteria	Rationales
20	C	5.2.2	A. Incorrect. Assessing solution design occurs before execution. Because resources are already confirmed and work is being performed, this step is not the primary activity described. "When an iteration of a product design is complete, the product team assesses the design and plans the building and testing activities." Ref 6.1 B. Incorrect. Planning and confirming resources precede execution. Because resources are already confirmed and work is being performed, this step is not the primary activity described. "When resource availability is confirmed, the building and testing activities are performed as planned." Ref 6.1 C. Correct. The scenario describes developing the feature, integrating it with other modules, performing unit and integration testing, validating security controls, and preparing operational documentation. These activities correspond directly to executing the planned build and testing work within the 'build' activity. "Execute building and testing plans." Ref 6.2 D. Incorrect. Delivery for transition occurs after building and testing are complete: "The products that are built and tested (along with the supporting documentation) are then shipped for transition..." execution is still in progress, not yet transitioned. Ref 6.1
21	D	5.3.1	A. Incorrect. Choosing a scalable architecture supports long-term growth, but the core issue here is unstable releases and manual deployment errors. "A solid 'build' activity starts with a comprehensive architecture that defines system components [...]". Ref 6.4.1 B. Incorrect. Dashboards and alerts improve operational visibility, but they do not prevent defects introduced during build and deployment. "Defining and continuously tracking KPIs [...] creates a data-driven baseline that highlights bottlenecks [...]". Ref 8.4.1 C. Incorrect. Documentation improves understanding, but it does not reduce defect leakage or manual deployment risks. "Detailed design specifications [...] serve as a shared reference [...] minimizing ambiguity and preventing costly rework [...]". Ref 6.4.1 D. Correct. The issue stems from defects, regressions, and manual effort; automation directly addresses this by validating every change before release. "Embedding unit, integration, and UI test suites within an automated CI pipeline guarantees that each code commit is validated against predefined quality gates." Ref 6.4.1

Question	Answer	Assessment Criteria	Rationales
22	C	6.1.2	A. Incorrect. Planning release timing helps coordinate deployment, but it does not ensure that performance and security requirements are validated before go-live. "Plan transition activities and confirm resource availability." This shows planning transition timing and coordination is part of transition planning, it is not validation of performance or security requirements. Ref 7.2 B. Incorrect. Preparing infrastructure supports technical readiness, but it does not confirm that the service meets agreed functional and non-functional requirements. "Infrastructure and platform management: Prepares infrastructure components (servers, cloud, networks) to support the transitioned product or service [...]" Ref 7.3, Table 7.2 C. Correct. The issue described (missed performance and security weaknesses) would have been prevented by structured validation against requirements before release. "Service validation and testing: Validates that the built product or service meets requirements, including performance and security criteria.." Ref 7.3, Table 7.2 D. Incorrect. Post-transition reviews improve future releases, but they occur after deployment and cannot prevent pre-release defects. "After a reasonable stabilization period, hold a retrospective focused on the transition itself." Ref 7.4.3
23	B	6.2.2	A. Incorrect. Assessing solutions and transition requirements occurs before planning detailed rollout activities. This step focuses on evaluating readiness and identifying transition needs. "The first step in moving a digital product from development to operation is a systematic assessment of the solution itself and the precise requirements that will enable a successful hand-off." Ref 7.2.1.1 B. Correct. This describes structured preparation for rollout, verification of monitoring, training readiness, and confirmation of operational resource availability. These activities align directly with the planning step. "Planning the transition begins by breaking down the high-level migration goal into discrete, time-boxed activities that can be tracked and owned." Ref 7.2.1.2 C. Incorrect. Execution would involve carrying out the deployment itself, activating the solution in live environments, and managing real-time issues during rollout. "The execution phase begins with a kick-off meeting that restates the overall goals, confirms that all prerequisites are ready, and defines a clear decision-making structure for the migration window." Ref 7.2.1.3 D. Incorrect. Communicating transition results happens after deployment activities are completed and outcomes are available for reporting. "Clear

Question	Answer	Assessment Criteria	Rationales
			communication of transition outcomes often starts with a brief executive summary that highlights overall results." Ref 7.2.14
24	A	6.3.2	A. Correct. The scenario highlights inconsistent configuration values, version mismatches, and unclear ownership just before go-live. Before approving release, Omar should ensure documentation, configuration records, and ownership responsibilities are aligned and consistent. This reduces transition risk and prevents operational confusion after deployment. "Freeze noncritical changes for complex transitions and adopt a release cadence." Ref 7.4.3, Table 7.4 B. Incorrect. This option reflects reactive control rather than preventive discipline. Monitoring improvements belong more appropriately to later operational or execution readiness refinements under 'Execute transition plans'. While improved monitoring can detect configuration problems, it does not resolve the underlying inconsistency or governance gaps before release. Transition guidance emphasizes resolving discrepancies and ensuring reliability before approving go-live rather than relying on detection after deployment. "The execution phase begins with a kick-off meeting that restates the overall goals, confirms that all prerequisites are ready, and defines a clear decision-making structure for the migration window." Ref 7.2.13 C. Incorrect. Additional integration validation relates to execution-level assurance under Execute transition plans. However, the problem described is not failed integration logic but inconsistent artifacts and unclear ownership. More testing would not correct version misalignment or governance gaps. The transition guidance stresses resolving structural readiness issues before execution rather than compensating with further testing "The first step in moving a digital product from development to operation is a systematic assessment of the solution itself and the precise requirements that will enable a successful hand-off." Ref 7.2.1.1 D. Incorrect. This option contradicts transition best practices. Approving release despite known inconsistencies conflicts with the intent of Assess solutions and transition requirements, which aims to minimize chaos and reduce risk before moving into production. Delaying documentation correction until after release increases operational uncertainty and undermines reliability. "The first step in moving a digital product from development to operation is a systematic assessment of the solution itself and the precise requirements that will enable a successful hand-off." Ref 7.2.1.1

Question	Answer	Assessment Criteria	Rationales
25	A	6.2.2	A. Correct. Assigning responsibility, estimating effort, and documenting dependencies to avoid bottlenecks is happening within the 'plan transition activities and confirm resource availability' step of the 'transition' activity. "Assign each task a responsible owner, an estimated effort, and a realistic deadline, ensuring that dependencies are explicitly captured to avoid bottlenecks." Ref 7.2.1.2 B. Incorrect. 'Operational' activity concerns running live products and ensuring performance and availability, not planning tasks, estimating effort, or mapping dependencies for implementation. "For every item, list the resources needed to execute it successfully. A daily health-check may require a monitoring engine, a set of synthetic probes, and a handful of engineers to review alerts. " Ref 8.2.1.2 C. Incorrect. Requirements assessment focuses on reviewing and validating design requirements before build, not assigning task owners and estimating effort. "The goal of assessing the solution design is to ensure: That the design requirements are clear and that the build specifications will contribute the expected value" Ref 6.2.1.1 D. Incorrect. IT asset management relates to managing the lifecycle of financially valuable components, not planning task ownership or effort estimation. IT asset management practice is "The practice of planning and managing the full lifecycle of all IT assets." Ref Glossary
26	B	7.1.2	A. Incorrect. Monitoring helps detect issues earlier, but it does not address the underlying causes of recurring disruptions. "This includes routine operational tasks such as monitoring, performance tuning, backups, housekeeping, and technical maintenance that prevent incidents and service degradation." This shows monitoring is part of routine operations, not root cause removal. Ref 8.1.2 B. Correct. The scenario describes repeated disruptions and declining reliability. The 'operate' activity aims to ensure products run as intended and prevent degradation. Addressing recurring issues improves reliability. "The purpose of the 'operate' activity is to maintain and monitor digital products and services and supporting systems, ensuring optimal performance and reliability." Ref 8.1.1 C. Incorrect. Applying temporary workarounds consistently may stabilize response, but it does not eliminate the recurring problem. "The 'operate' activity covers the ongoing technical and operational work required to keep the product reliable, secure, and performant in live use." Ref 8.1.2 D. Incorrect. Reviewing data supports analysis, but without addressing root causes, reliability will

Question	Answer	Assessment Criteria	Rationales
			continue to decline. The key metric of success include "Live products' reliability, performance, and information security." Ref 8.1, Table 8.1
27	B	7.2.1	A. Incorrect. Updating procedures reflects improvement work, not the direct output of daily monitoring. One of the key outputs of 'operate' are "Product performance records and reports." Ref 8.1, Table 8.1 B. Correct. The scenario describes observing system behaviour, tracking thresholds, and recording disruptions, and these directly produce monitoring data and performance records as outputs of the 'operate' activity. "Operating products and services; Monitoring data and performance reports; Event data and event processing records; Incident records". Ref 8.2.2 C. Incorrect. The scenario describes monitoring, tracking performance, and recording disruptions to ensure reliability. This aligns with the purpose of the 'operate' activity, which focuses on keeping the product running reliably in live use. Creating workarounds and known-issue records is primarily associated with restoring service and preventing recurrence (support/problem management), not with the core output of routine operational monitoring. "The 'operate' activity covers the ongoing technical and operational work required to keep the product reliable, secure, and performant in live use." Ref 8.1.2 D. Incorrect. Improvement recommendations may result from later analysis, but the immediate output of monitoring is performance and event records. "Measurement and reporting: Monitoring service performance, incidents, and operational trends." Ref 8.3, Table 8.2
28	C	7.2.2	A. Incorrect. This option does not fit because the scenario does not describe reporting outcomes of any lifecycle event. It focuses on organizing operational routines rather than communicating results. Additionally, the question is explicitly about 'operate'. This is the step of 'transition' activity. "Clear communication of transition outcomes often starts with a brief executive summary that highlights overall results, any departures from the original plan, and the business impact of the migration." Ref 7.2.1.4 B. Incorrect. Execution in 'operate' refers to actively running monitoring systems, responding to alerts, and performing corrective actions. In the scenario, the team is not responding to live issues or performing remediation. Instead, they are defining recurring activities and confirming accountability. That indicates planning within 'operate', not execution. "A resilient system depends on a repeatable schedule of operational tasks that keep the platform secure, performant, and cost-effective." Ref 8.2.1.2

Question	Answer	Assessment Criteria	Rationales
			C. Correct. The scenario describes establishing a structured cadence of recurring platform activities, identifying required tools and expertise, and assigning formal accountability. This aligns directly with the 'operate' step that focuses on organizing repeatable operational work and confirming that appropriate skills and resources are available before execution. The emphasis is proactive structuring and resource validation, not reactive monitoring or reporting. "A resilient system depends on a repeatable schedule of operational tasks that keep the platform secure, performant, and cost-effective." Ref 8.2.1.2 D. Incorrect. This would involve reporting performance metrics or service outcomes to management or customers. The scenario does not describe performance reporting. It focuses on structuring operational routines and confirming readiness. Therefore, it does not align with this step. "The daily operational schedule helps to keep the service healthy, surface early-warning signs, and align the team with the organization's strategic objectives." Ref 8.2.1.3
29	D	7.3.1	A. Incorrect. Elastic infrastructure improves scalability, but the core issue described is lack of visibility and shared understanding of service health. "Scalable infrastructure and capacity planning: Infrastructure that can elastically scale while preserving performance and cost efficiency [...]". Ref 8.4.1 B. Incorrect. Feeding lessons learned into safeguards strengthens resilience, but the scenario highlights fragmented monitoring and reactive decisions rather than post-incident learning gaps. "Embedding lessons learned back into monitoring thresholds, runbooks, and code safeguards ensures that each disruption becomes a prompt to increase resilience." Ref 8.4.1 C. Incorrect. Security controls are important, but the instability described stems from poor operational visibility and reactive management, not compliance gaps. "Security-first culture and compliance governance: [...] ensure that operational processes remain aligned with evolving legal and industry standards". Ref 8.4.1 D. Correct. The situation clearly reflects a lack of shared metrics and holistic visibility; the critical success factor directly addresses this. "End-to-end process visibility and metrics: A holistic view of the entire product lifecycle and continuously tracking metrics aligns teams around shared service-level goals." Ref 8.4.3, Table 8.4

Question	Answer	Assessment Criteria	Rationales
30	B	7.3.2	A. Incorrect. This recommendation relates to ensuring data quality and governance before introducing advanced analytics or AI capabilities. The scenario does not mention AI-related risks or poor data structures affecting machine learning outcomes. The problem described is architectural shortcuts and operational instability due to technical debt, not data readiness for AI. Therefore, this option does not address the root cause. "Many organizations try to implement AI before organizing their operational data landscape. Without event correlation, governance, and standardization, AI tools turn into 'slop' generators and noise amplifiers." Ref 8.4.3 B. Correct. The scenario describes accumulated architectural compromises, incomplete documentation, and unresolved shortcuts that were introduced under time pressure and never systematically addressed. Over time, this has led to instability, slower recovery, and poor understanding of dependencies. This has created technical debt which has to be reviewed and corrected. "Acknowledge and treat technical debt as a serious risk (visible, shared tracking across product/ops/service)". Ref 8.4.3, Table 8.4 C. Incorrect. Balancing quality and speed is a general principle in product management. However, the scenario shows that speed was prioritized at the expense of long-term stability and hence created technical debt. Simply focusing on "quality and speed" does not provide a concrete mechanism for identifying, tracking, and resolving accumulated structural weaknesses. The issue requires systematic recognition and collaborative remediation, not a generic emphasis on balance. "Use observability tools to monitor not only infrastructure, but also components tied to customer satisfaction, such as response times, feature adoption, and error frequency." Ref 8.4.3 D. Incorrect. This recommendation concerns structuring teams appropriately to fit organizational needs and governance models. While team structure can influence effectiveness, the scenario's primary issue is unresolved structural weaknesses (technical debt) in the platform. Adjusting team design would not directly resolve undocumented compromises and hidden dependencies. The problem requires visible tracking and joint accountability for structural remediation rather than organizational restructuring. "Operational maturity depends on having a team topology that fits the business environment." Ref 8.4.3

Question	Answer	Assessment Criteria	Rationales
31	C	8.1.2	A. Incorrect. Incident management focuses specifically on restoring normal service operation after incidents occur. "This includes agreeing on who is accountable for availability, performance, and support; user communication; delivery of goods, and fulfilment of service requests." Ref 9.1.2.3 B. Incorrect. Service request management handles fulfilment of requests, but the scenario describes a centralized team receiving, recording, assisting, and routing interactions, something which aligns more directly with the service desk function. "As a minimum, this channel is used for consultations and feedback." This shows interactions include consultations and feedback, beyond simple request fulfilment. Ref 9.1.2.1 C. Correct. The service desk is defined as the single point of contact that captures and routes incidents and service requests, and this precisely reflects the scenario. "‘Deliver’ aims to ensure that services based on the product are provided reliably, safely, and in line with agreed expectations, across all relevant touchpoints.”. Also, this “includes providing access to the product through agreed interfaces (usually, apps and web), ensuring appropriate support and guidance.”. This directly supports the role of a centralized contact point providing guidance and support, the service desk. Ref 9.1.2 D. Incorrect. Relationship management focuses on maintaining ongoing value co-creation between provider and consumer, not day-to-day user contact handling. Service relationship management is when joint "activities performed by a service provider and a service consumer to ensure continual value co-creation based on agreed and available service offerings". Also, the "purpose of the 'deliver' activity is to provide products and services to users, manage user onboarding/offboarding, maintain service quality standards, and gather consumer feedback." Ref Glossary, 9.1.1
32	C	8.2.1	A. Incorrect. Although listed as an output, the scenario describes creating/adapting the delivery plan itself rather than assessing readiness. The 'delivery' outputs include: "delivery readiness assessment report, delivery plans and procedures, delivered services". Ref 9.2.2 B. Incorrect. Feedback is captured after execution: "Delivery does not end with fulfilment; it also involves [...] gathering user feedback". Ref 9.2.1.3 C. Correct. The scenario describes reviewing commitments (SLAs, service requests, events) and then deciding how services will be delivered and what resources are required. This corresponds to Step 2 of the 'deliver' activity: "Identify and confirm delivery plan and resource availability",

Question	Answer	Assessment Criteria	Rationales
			"Once commitments are clear, providers create or adapt a delivery plan. This involves confirming the procedures, tools, and resources". Ref 9.2, 9.2.1.2 D. Incorrect. Performance reports are produced after execution and reporting: "The key output of the 'deliver' activity is the delivered services. Other outputs include: [...] service performance and user feedback records and reports". Ref 9.2.2
33	A	8.2.2	A. Correct. This focuses on reviewing service level agreements, verifying solution capability against commitments, and ensuring readiness before activating customer access. "'Deliver' begins by reviewing the commitments defined in service agreements. This includes assessing SLAs, service requests, and events that may impact delivery." Ref 9.2.1.1 B. Incorrect. This step of the workflow focuses on planning execution and confirming resources. "Once commitments are clear, providers create or adapt a delivery plan. This involves confirming the procedures, tools, and resources (such as staff, suppliers, and automation capabilities) required to meet commitments. Plans also establish roles and responsibilities to ensure accountability during delivery." Although confirming support agent scheduling is mentioned, the primary focus is on reviewing commitments and solution readiness, not defining or confirming a structured delivery execution plan. Ref 9.2.1.2 C. Incorrect. Execution occurs when delivery activities are actively performed and status is reported. "The final step is execution: fulfilling service requests, carrying out onboarding and offboarding, or completing scheduled service actions." Ref 9.2.1.3 D. Incorrect. Vendor-partner responsibilities relate to delivery perspectives. "Because the user's experience is shaped by both the product capabilities and how services are delivered around it, a clear definition of responsibilities between the vendor and partner service providers is crucial." Ref 9.1.2.3
34	B	8.3.1	A. Incorrect. Increasing automation does not directly address confusion, trust erosion, or change fatigue during frequent delivery updates. "Modern delivery increasingly makes use of AI-driven capabilities such as chatbots, virtual agents, and predictive request routing. [...] . However, automation must be balanced with human interaction. Consumers expect empathy and transparency, especially in moments of disruption or uncertainty. The responsible use of AI enhances efficiency without eroding trust". Ref 9.1.3 B. Correct. Applying improvements to a limited group and adjusting based on feedback directly addresses change fatigue and dissatisfaction during frequent updates. "Prevent change fatigue

Question	Answer	Assessment Criteria	Rationales
			[...] Consumer satisfaction during delivery changes; staff engagement scores; reduction in complaints linked to delivery changes". and "Apply change enablement to delivery process changes. Test changes with pilots. Use transparent communication strategies." Ref 9.4.2, 9.4.3 C. Incorrect. Service agreements define expectations and responsibilities. However, the scenario describes confusion and declining satisfaction during periods of frequent delivery updates. Updating documentation of agreements does not directly address how delivery changes are introduced, paced, or experienced. "Delivery starts with clarity. Agreements (whether formal SLAs, contracts, terms and conditions accepted by customers and users, or informal commitments), define and/or imply the outcomes, responsibilities, and expectations that guide how services will be provided." Ref 9.1.3 D. Incorrect. Delivery already includes gathering user feedback as part of normal execution. The scenario indicates that feedback has been received and highlights confusion and declining satisfaction during frequent updates. Expanding surveys increases feedback collection but does not directly address how delivery changes are introduced, paced, or managed. "Delivery does not end with fulfilment; it also involves capturing evidence, reporting outcomes, and gathering user feedback. This ensures that delivery performance is visible, measured, and ready to inform continual improvement." Ref 9.2.1.3
35	B	8.3.2	A. Incorrect. The practical recommendations do not suggest maximizing automation at the expense of human access. Increasing automation without escalation pathways contradicts this recommendation. "Deploy AI-enabled self-service for common requests but define escalation thresholds to ensure users can always reach a person when required." Ref 9.4.3 B. Correct. This highlights declining satisfaction due to lack of human escalation. "Deploy AI-enabled self-service for common requests but define escalation thresholds to ensure users can always reach a person when required." This action directly addresses the issue by balancing automation efficiency with accessible human support, aligning fully with the book's guidance. Ref 9.4.3 C. Incorrect. Delivery recommendations emphasize structured evaluation and governance rather than reducing oversight. "Use the Four Dimensions as a checklist during delivery planning and reviews." Ref 9.4.3 D. Incorrect. The recommendations focus on managing delivery experience and avoiding

Question	Answer	Assessment Criteria	Rationales
			disruption, not withholding value until automation is maximized. "Apply change enablement to delivery process changes." Ref 9.4.3
36	C	9.1.2	A. Incorrect. Deploying fixes quickly focuses on restoration speed rather than structured risk evaluation before implementation. "Respond to incidents/disasters and restore normal operations and delivery." Rapid restoration is part of incident response. The scenario highlights the need to analyse risks before applying changes to the live environment. Ref 10.2 B. Incorrect. Monitoring impact after implementation verifies outcomes but does not ensure that risks are assessed prior to deployment. "Review and report support actions." Review activities occur after response and restoration steps. The situation requires structured control before changes are introduced. Ref 10.2 C. Correct. Change enablement provides structured evaluation and authorization of changes prior to deployment into the live environment. "Change enablement: Implementing changes in the live environment required to resolve incidents and execute the disaster recovery plans." Applying structured evaluation and authorization before implementing fixes ensures alignment with risk policies and business impact. Ref 10.3 D. Incorrect. Analysing underlying causes supports improvement but does not replace change authorization prior to deployment. "Investigating incidents, detecting product and service errors and initiating improvements." Ref 10.3, Table 10.2
37	C	10.2.1	A. Incorrect. Creation refers to generating new outputs rather than analysing patterns. "AI generates net-new outputs in response to prompts or triggers." Ref 1.4, Table 1.2 B. Incorrect. Clarification focuses on improving understanding of existing content, not identifying patterns. "AI helps users find, understand, navigate, or improve existing content by summarizing, rephrasing, restructuring, or translating it." Ref 1.4, Table 1.2 C. Correct. Cognition involves detecting patterns and enabling proactive analysis. "AI identifies patterns, anomalies, or hidden insights across data, enabling proactive detection, forecasting, and analysis." Ref 1.4, Table 1.2 D. Incorrect. Communication refers to acting as an interface for interaction, not analytical detection. "AI acts as a communicative interface helping users interact with services and systems naturally." Ref 1.4, Table 1.2

Question	Answer	Assessment Criteria	Rationales
38	A	9.2.2	A. Correct. This focuses on detection, impact evaluation, classification, and prioritization of the issue. "Detection starts with a unified observability platform that streams logs, metrics, traces, and partner-level SLA data into a central incident management system." Ref 10.2.1.1 B. Incorrect. This step occurs after identification and assessment, when corrective actions are taken. Restoration has not yet begun; the team is still evaluating impact and priority. "Once an incident is classified, the responsible lead activates the appropriate run-book through a single click in the ticketing system." Ref 10.2.1.2 C. Incorrect. Review and reporting happen after response activities are completed. There is no indication that resolution has occurred or that post-incident reporting is underway. "When normal service is restored, an analytics pipeline pulls together logs, ticket histories, run-book execution timestamps, and the sync briefs generated during the response." Ref 10.2.1.3 D. Incorrect. This option refers to the 'operate' activity, not 'support'. Incident detection and assessment belong to the support workflow, not routine operational execution. "The daily operational schedule helps to keep the service healthy, surface early-warning signs, and align the team with the organization's strategic objectives." Ref 8.2.1.3
39	A	10.1.1	A. Correct. The operating model described corresponds to custom software development for specific enterprise customers, where responsibility for transition is shared. "To develop and ship software to meet specific customer's requirement. 'Design', 'acquire', 'build', 'transition' (partially). Discover: customers. Transition: jointly with customers and/or third parties." Ref 11.3, Table 11.2 B. Incorrect. Business users are involved in later lifecycle activities, but they are not solely responsible for transition. "Deliver, support: customers." This indicates that customers are typically responsible for deliver and support in this pattern, not exclusively for transition. Ref 11.3, Table 11.2 C. Incorrect. The development team alone does not carry full responsibility for transition in this operating model. "'Design', 'acquire', 'build', 'transition' (partially)." Transition is described as only partially within the vendor's scope, demonstrating that it is not executed solely by the software development team. Ref 11.3, Table 11.2 D. Incorrect. An external managed service provider is responsible for transition in a different value chain pattern. "Acquire, transition, operate: external managed service providers." This responsibility applies to a pattern focused on third-party

Question	Answer	Assessment Criteria	Rationales
			technology services, not to the custom enterprise development model described in the scenario. Ref 11.3, Table 11.2
40	C	10.2.5	A. Incorrect. Project management is not described as governing daily service operations. ITIL Service addresses delivery and operational support, whereas project management is categorized as a general management practice. "General management practices: can be applied to any product or service, as well as an organization's general management activities." Ref 12.3 B. Incorrect. Project management is presented as one of the ITIL management practices, not as a replacement for product and service management practices. ITIL includes multiple practices that collectively enable value creation. "ITIL includes 34 management practices combined in two groups: Product and service management practices [...] General management practices [...]" Ref 12.3 C. Correct. Project management is important because organizations constantly implement change and transformation. ITIL highlights structured transformation guidance and compatibility with other bodies of knowledge used in digital transformation journeys. "While ITIL focuses on the digital product and services management, PRINCE2 equips professionals with the tools to manage projects that implement or transform those products and services, as well as changes to the value system." Ref 12.4.2 D. Incorrect. Service level targets and metrics are associated with specific ITIL management practices, not with project management replacing or defining operational metrics. "ITIL includes 34 management practices combined in two groups: Product and service management practices [...] General management practices [...]" Ref 12.3

This image shows a blank sheet of white paper with horizontal purple lines. A light gray diagonal shape is visible on the right side of the page. The lines are evenly spaced and extend across the width of the paper. The gray shape starts from the bottom right corner and extends upwards towards the top right corner, creating a triangular area.
